# Presentation outline

- Balancing analysis
- Technical background

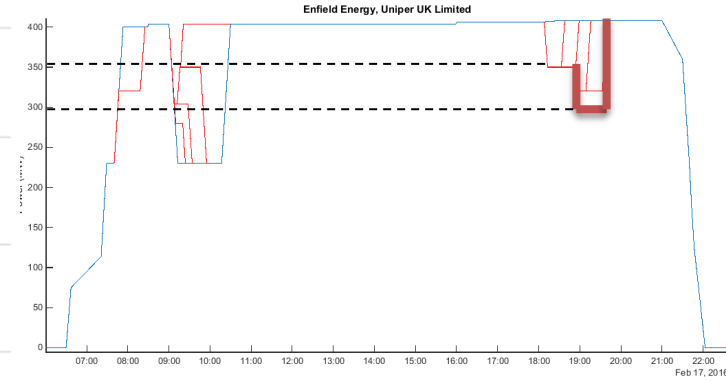

## Balancing analysis

# Balancing analysis

Source: [bmreports.com](http://bmreports.com)

# Balancing analysis – operational map

Example:

- 350 – 300 MW

Options to reduce load:

- Constant TET
- Constant Texhaust
- Constant VIGV<sup>o</sup>
- Custom

# Balancing analysis – operational map

Operational strategy is

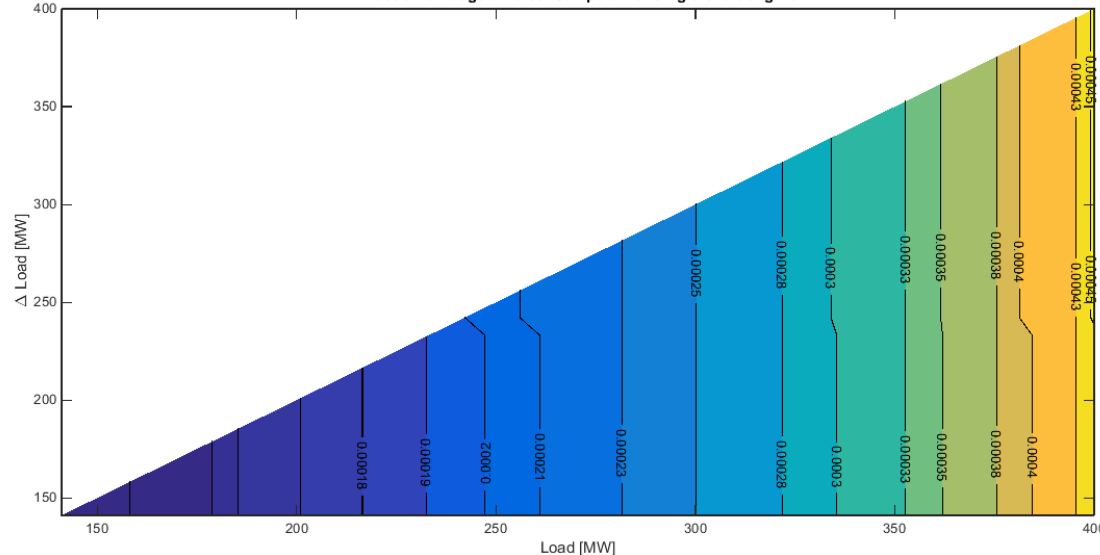

Life analysis ...

# Balancing analysis - fatigue

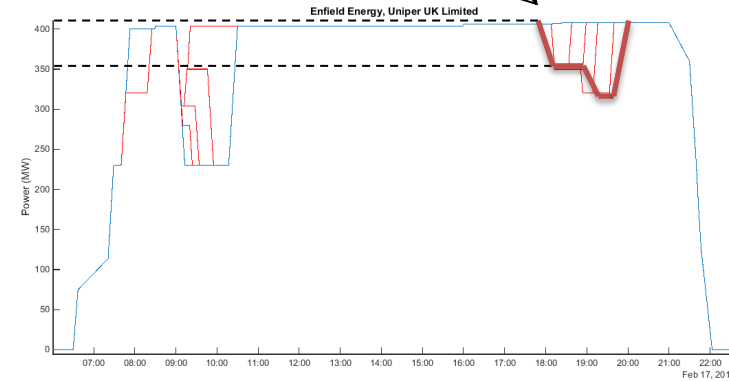

Fraction of fatigue life consumed for multi-shaft engine

Fraction of fatigue life consumption for single-shaft engine

National Grid asks:

Example:

**First**

- 400 – 350 MW **0.045% fatigue consumption**
- Hold for 1 hour **consumption**

**Then**

- 350 – 300 MW **0.033% fatigue consumption**
- Hold for 1 hour **consumption**

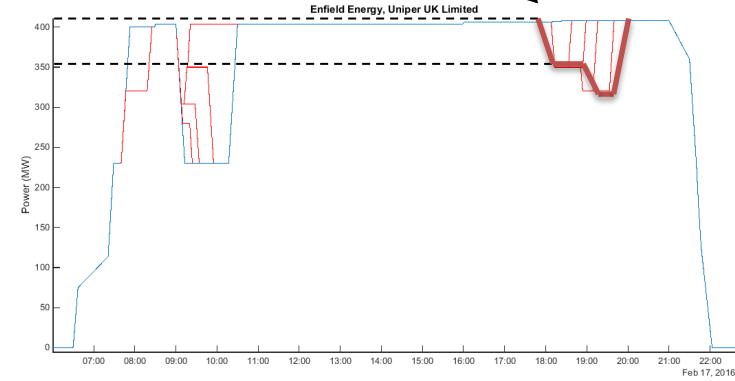

**TOTAL: 0.078%**

x 500 times

**39% fatigue consumption**

# Balancing analysis - creep

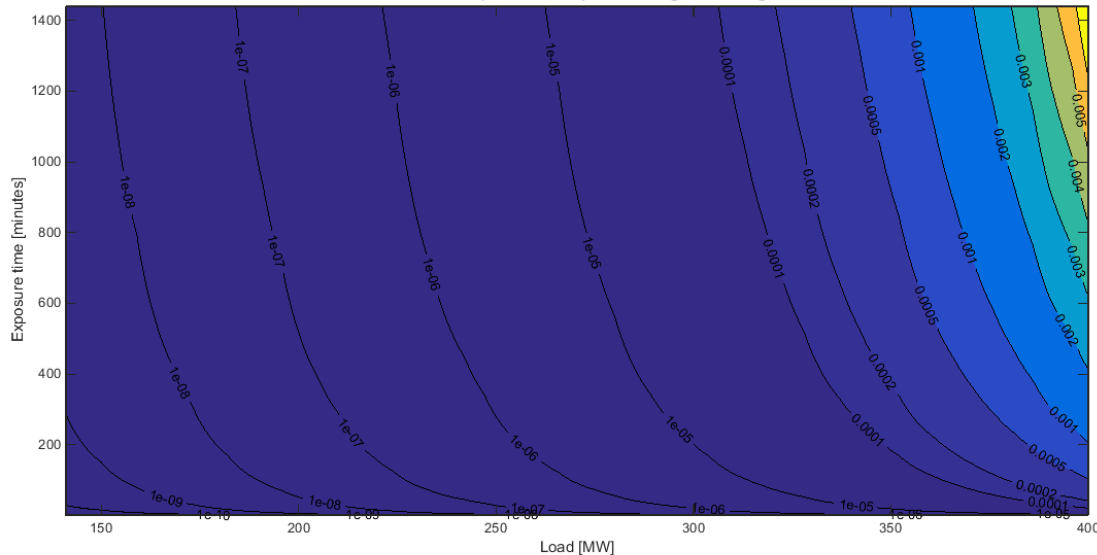

National Grid asks:

Fraction of creep life consumption for multi-shaft engine

Fraction of creep life consumption for single-shaft engine

Example:

**First**

- 400 – 350 MW 0.004% creep consumption
- Hold for 1 hour

**Then**

- 350 – 300 MW 0.0005% creep consumption
- Hold for 1 hour

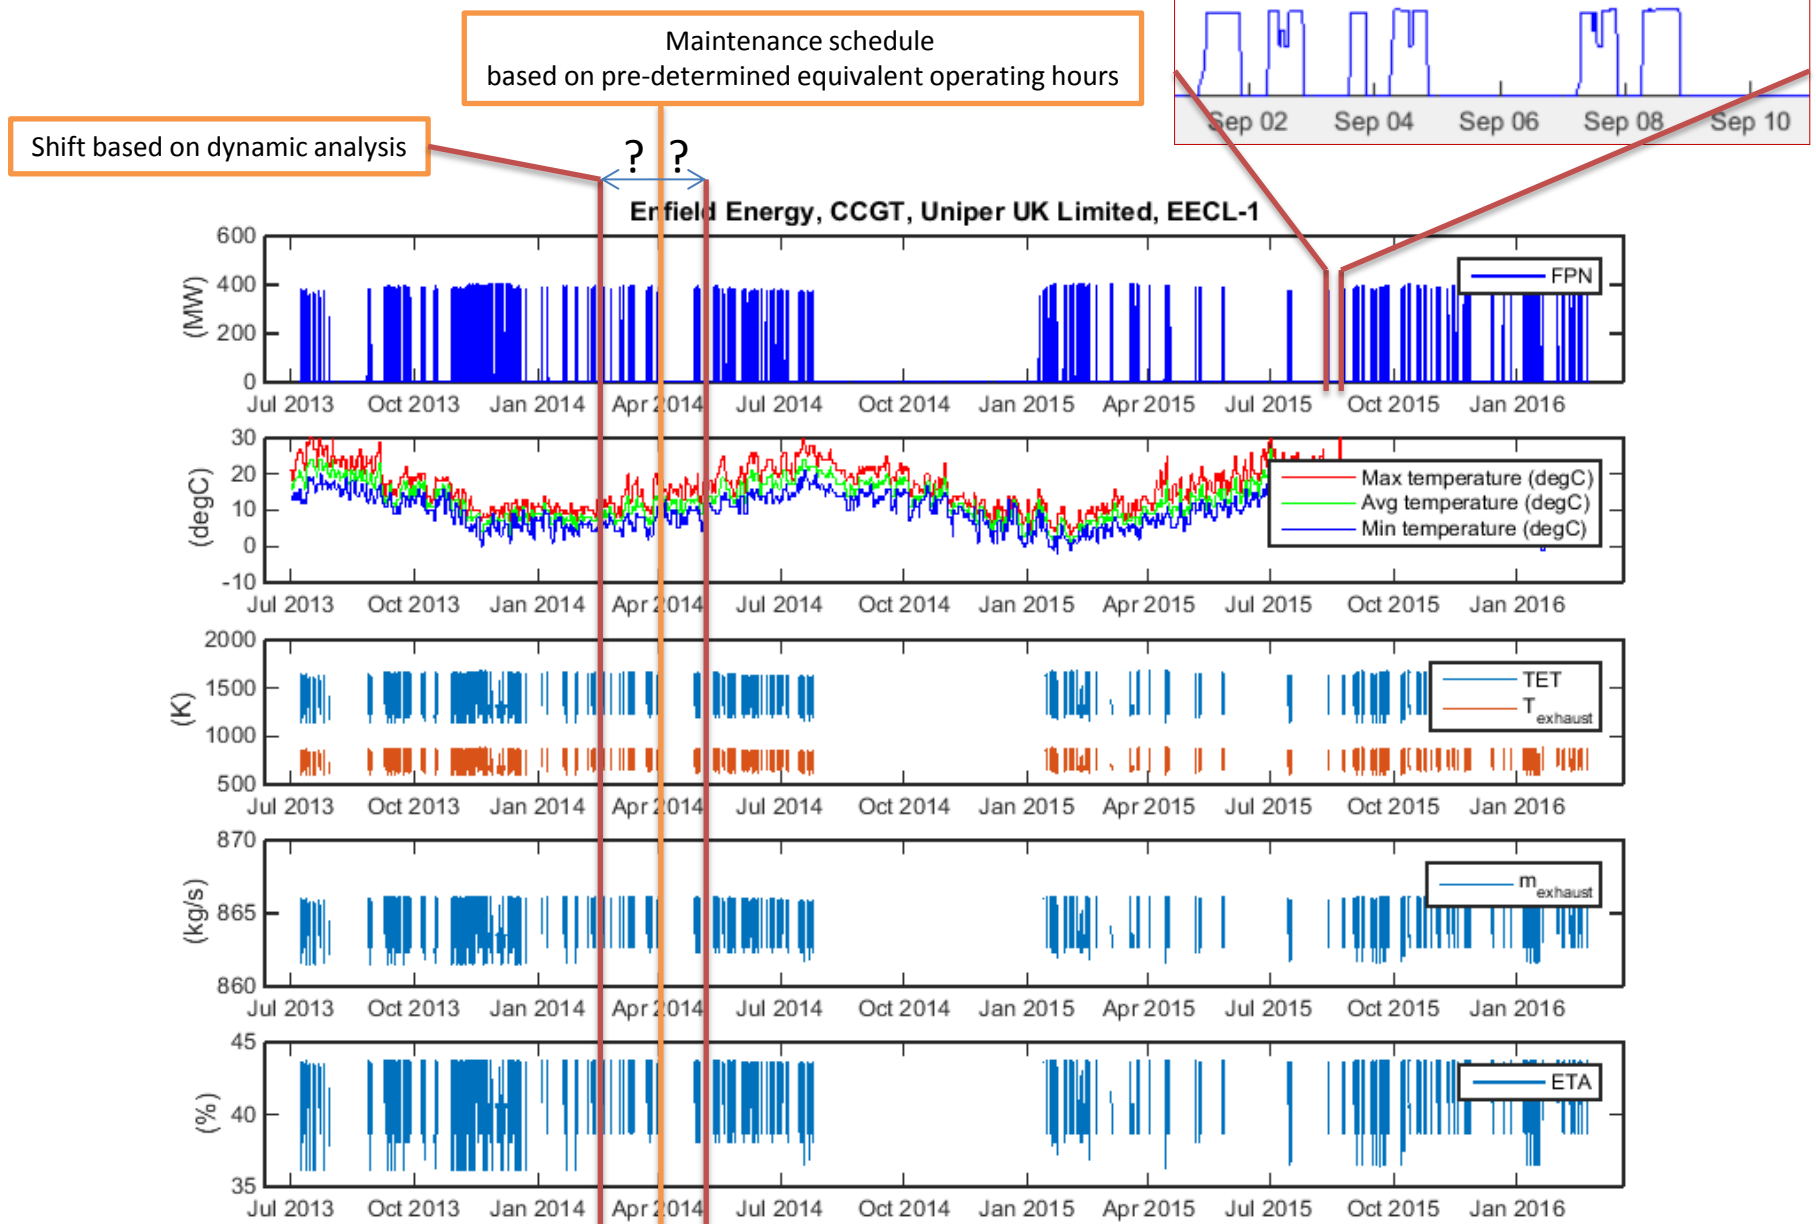

**TOTAL: 0.00455%**

x 500 times

**2.3% creep consumption**

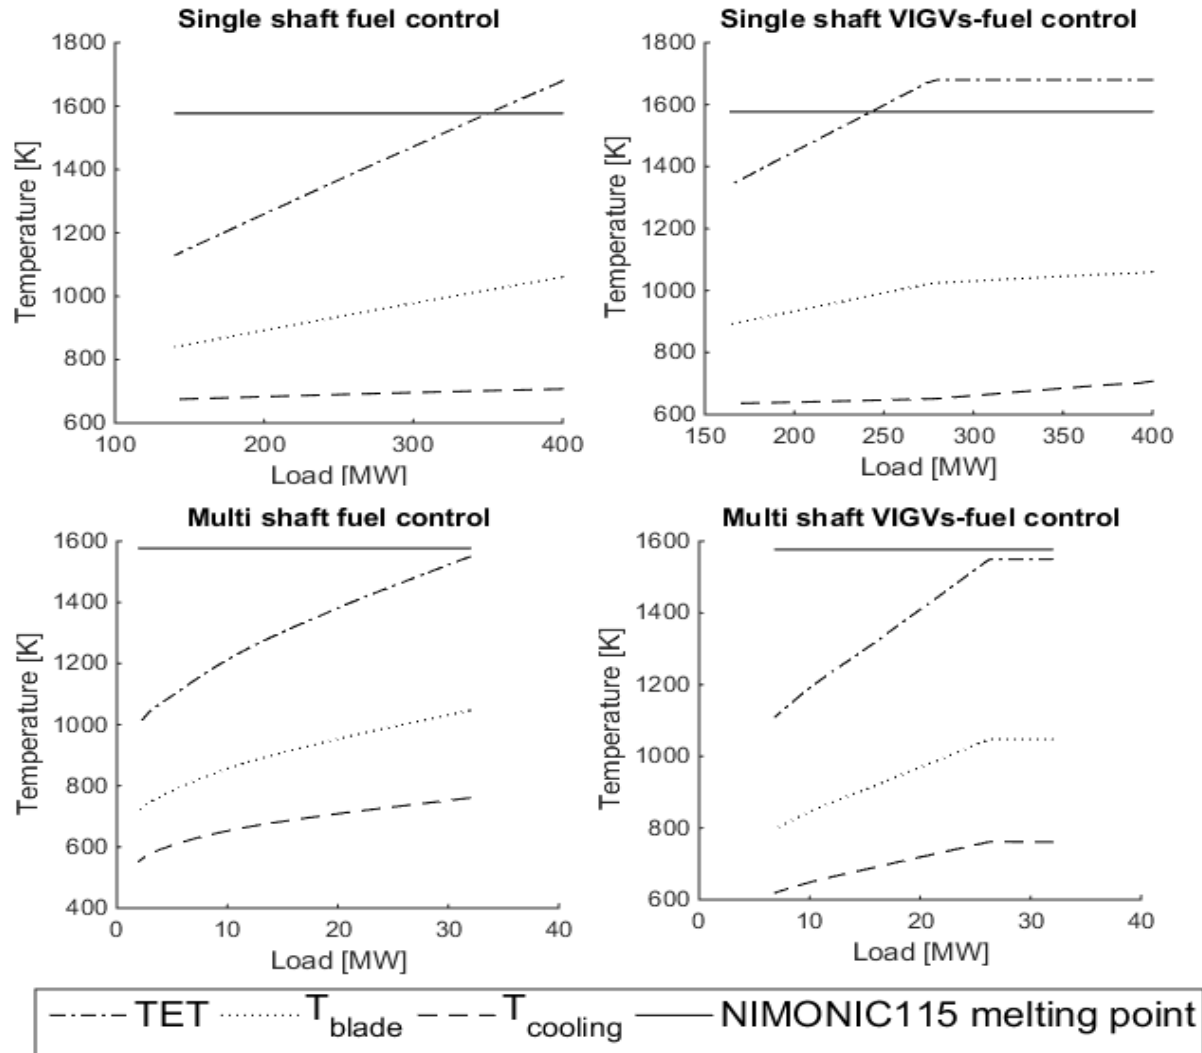

# Global balancing analysis

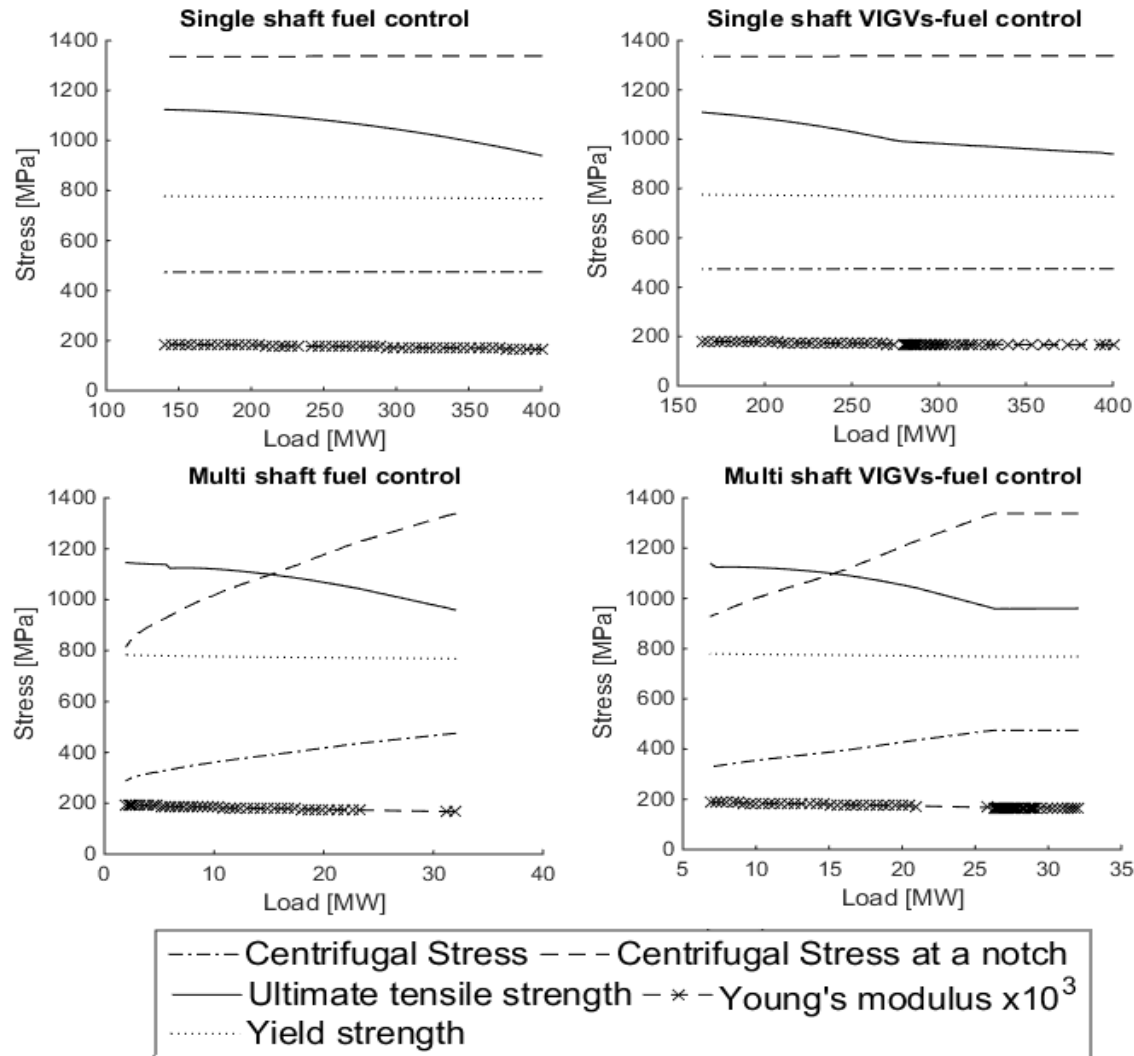

Technical background

# Gas turbine performance

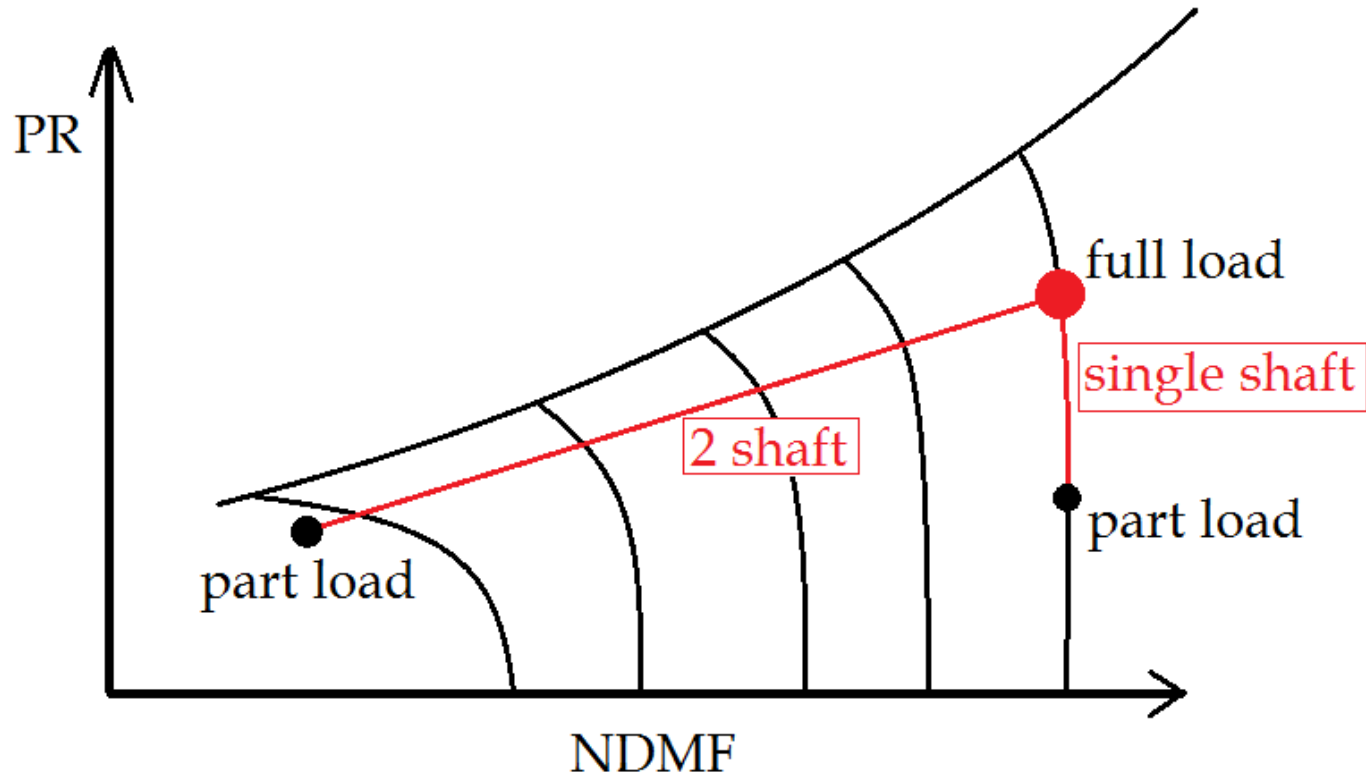

# Gas turbine performance

Technical background  
– development of operational map

# GT Simulation

# GT simulation

## Load reduction methods

1. Fuel active control
2. Turbine entry temperature control
  - $TET = \text{const.} \rightarrow Texh \text{ increase}$
3. Exhaust temperature control
  - $Texh = \text{const.} \rightarrow TET \text{ decrease}$

# GT engine operational map

## Risks

### **VIGV control only**

- Overheating the hot section

### **Fuel control only**

- Flame out due to excessively lean conditions

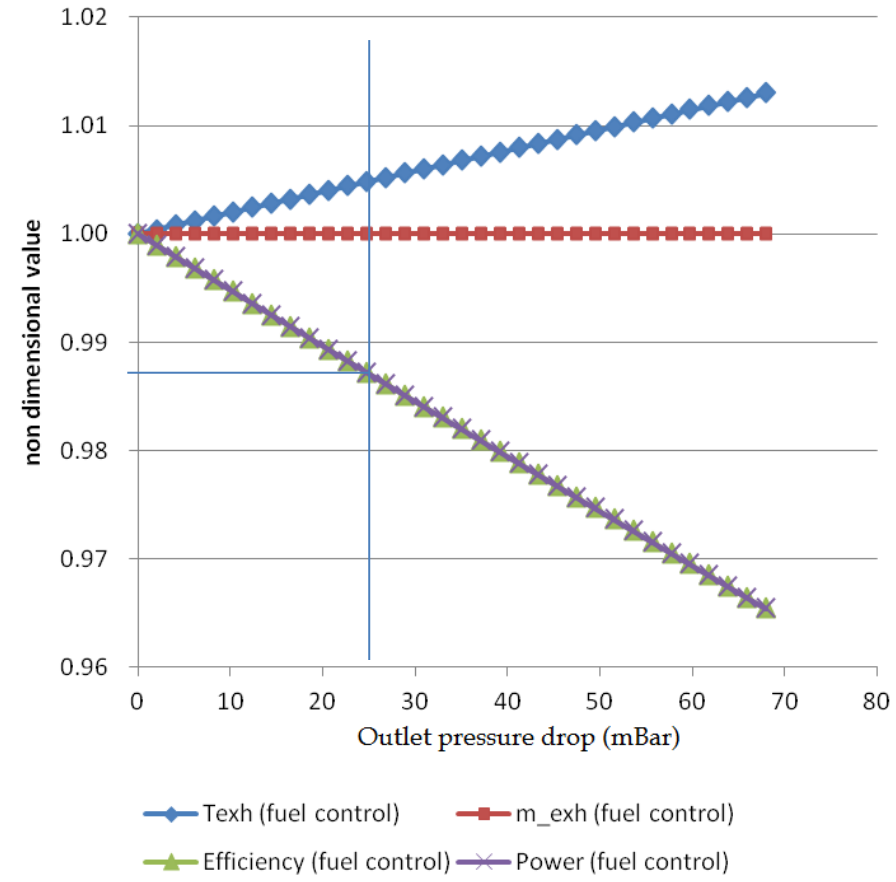

# GT simulation

## Inlet Pressure Drop Effect

~ 2% Power loss

## Outlet Pressure Drop Effect

~ 1% Power loss

# GT simulation

## Ambient Temperature Effect

- ◆ Texh (fuel control)
- m\_exh (fuel control)
- ▲ Efficiency (fuel control)
- × Power (fuel control)

~ 10% Power loss

## Ambient Pressure Effect

- × Power (fuel control)
- m\_exh (fuel control)
- ▲ Efficiency (fuel control)
- ◆ Texh (fuel control)

~ Power loss in bottoming cycle

# GT engine operational map

## Case scenario

- 10 mbar drop at inlet (inlet filter)
- 25 mbar drop in exhaust back pressure (HRSG)
- Ambient temperature increase from 15°C – 25°C

13% power loss  
e.g. 52 MW lost in 400 MW plant

## Conclusion:

Non-dimensional mass flow should represent x-axis in GT Operational Map,  
not power output

# GT engine operational map

- **D**
- **N**
- Fuel flow
- VIGV
- PO
- **T amb**
- **P amb**
- Load exposure time
- Load change
- Fatigue life consumption
- Creep life consumption

$$\pi_1 = \frac{\dot{m}_{GT} \sqrt{T_{amb}}}{P_{amb}}$$

$$\pi_2 = \frac{TET}{T_{amb}}$$

$$\pi_4 = VIGV$$

$$\pi_3 = \frac{T_{amb}^{3/2} PO_{GT}}{DP_{amb}}$$

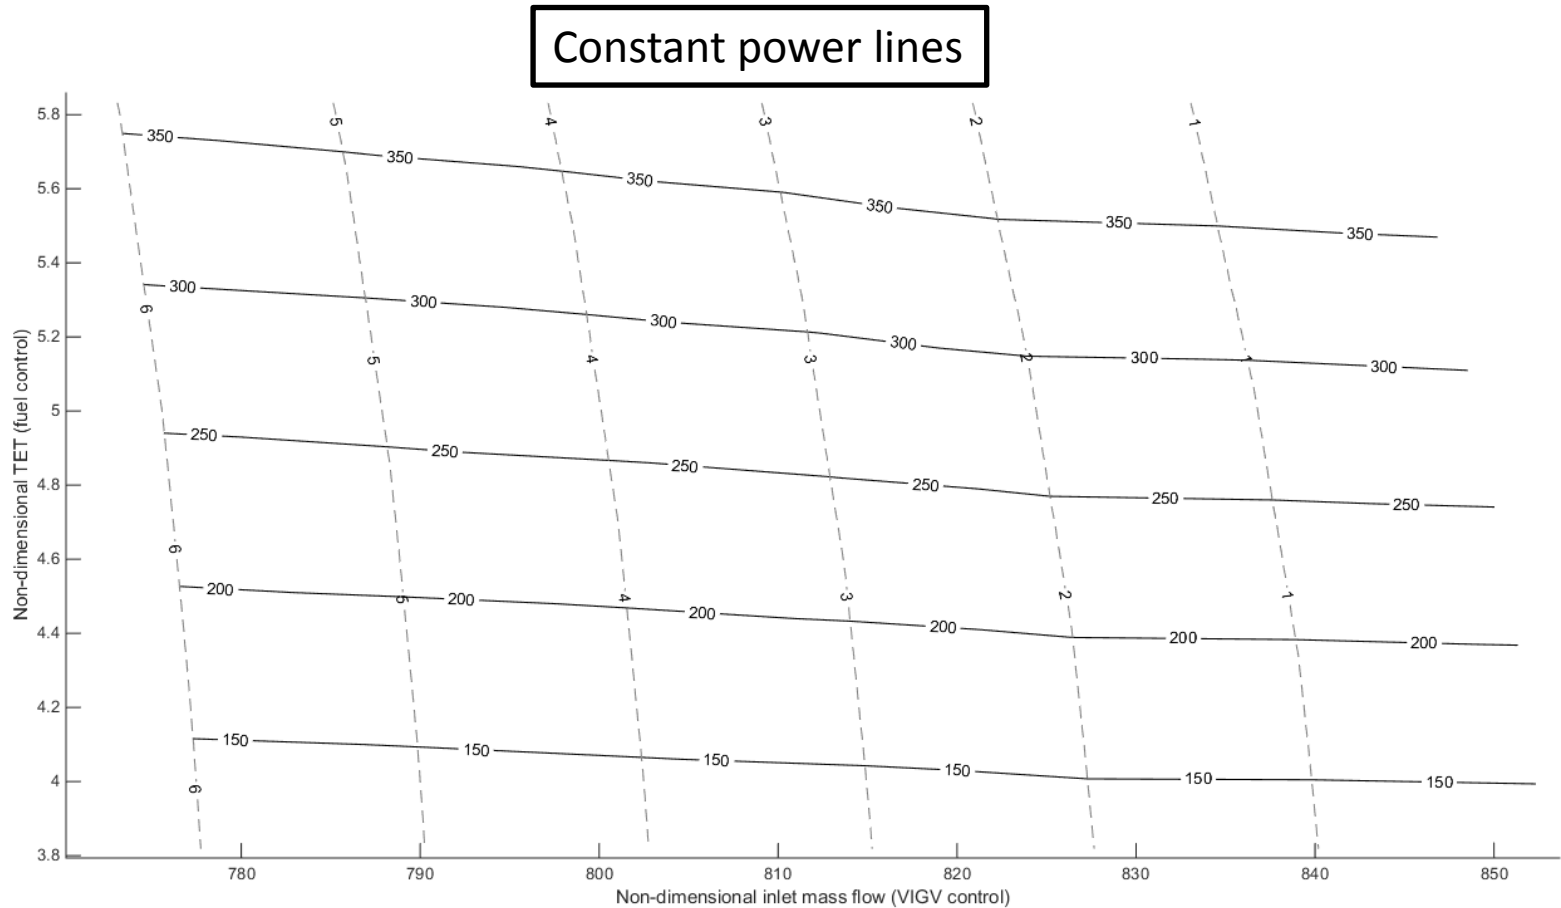

$$\pi_5 = ETA_{GT}$$

# GT engine operational map
